This print-out should have 50 questions. Multiple-choice questions may continue on the next column or page - find all choices before answering.

## $001 \quad 10.0$ points

A reaction has a negative change in entropy. This reaction can only be spontaneous if...

1. heat is absorbed by the system at any temperature

## 2. heat is released at any temperature

3. heat is absorbed at a sufficiently high temperature
4. None of these choices are correct because a reaction with a negative change in entropy can never be spontaneous
5. heat is released at a sufficiently low temperature correct

## Explanation:

A reaction must have at least one favorable term between entropy and enthalpy in order to be spontaneous. The negative entropy term is unfavorable, meaning the reaction must be exothermic (heat is released). Moreover, the reaction will only have a negative free energy change if the temperature is small enough. Conceptually, this is because the energy must be able to flow from the system to the low temperature surroundings.

002 (part 1 of 2) $\mathbf{1 0 . 0}$ points
Use the following phase diagram for the next two questions.

What is the normal melting point for this substance? Note: the vertical axis is logarithmic in scale.

1. $150^{\circ} \mathrm{C}$
2. $45^{\circ} \mathrm{C}$
3. $120^{\circ} \mathrm{C}$
4. $20^{\circ} \mathrm{C}$ correct
5. $75^{\circ} \mathrm{C}$
6. $0^{\circ} \mathrm{C}$

## Explanation:

The normal melting point is the point on the line where the solid and liquid phases coincide at 1 atm . This is found just less than halfway between the 0 and $50^{\circ} \mathrm{C}$ gridlines.

## 003 (part 2 of 2) 10.0 points

A sample of this substance is held at 0.1 atm and $-50^{\circ} \mathrm{C}$. The sample is pressurized to 3 atm and then heated to $250^{\circ} \mathrm{C}$. In total, what phase transitions occurred?

1. melting and boiling correct
2. sublimation only
3. sublimation and condensation
4. melting and condensation
5. melting and freezing

## Explanation:

Pressurizing from 0.1 atm to 3 atm does not result in a change of phase. However, heating to $250^{\circ} \mathrm{C}$ results in the melting of the solid followed by the vaporization of the liquid.
$004 \quad 10.0$ points
The following diagram shows a solution on the left (dark shade) and just the solvent on the right (light shade) separated by a semipermeable membrane.

Which diagram best represents the final state of this system after equilibrium is achieved?

## Explanation:

Only the solvent goes through the membrane thus increasing the volume on the solution side and decreasing volume on the solvent side. The solution side is therefore diluted slightly and the shade is lightened somewhat. The solute itself (the darker color) cannot pass through the membrane so the right side MUST also stay the same color of pure solvent (the lighest shade shown).

## $005 \quad 10.0$ points

Consider the following substances: acetic acid $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$, propane $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$, and acetone $\left(\mathrm{CH}_{3} \mathrm{COCH}_{3}\right)$. The boiling points (in no particular order) are $-42^{\circ} \mathrm{C}, 56^{\circ} \mathrm{C}$, and $118^{\circ} \mathrm{C}$. The vapor pressures (in no particular order) are 225 Torr, 15 Torr, and 6400 Torr. What is the boiling point and vapor pressure for acetic acid?

1. $118^{\circ} \mathrm{C}, 6400$ Torr
2. $-42^{\circ} \mathrm{C}, 6400$ Torr
3. $56^{\circ} \mathrm{C}, 225$ Torr
4. $-42^{\circ} \mathrm{C}, 15$ Torr

## 5. $118^{\circ} \mathrm{C}, 15$ Torr correct

## Explanation:

Of the three compounds listed, acetic acid has the strongest IMFs (hydrogen bond). This will correspond to the lowest vapor pressure and highest boiling point: 15 Torr and $118^{\circ} \mathrm{C}$.

## $006 \quad 10.0$ points

The enthalpy of vaporization of a liquid is measured to be about $28.4 \mathrm{~kJ} / \mathrm{mol}$ and its normal boiling point is $128^{\circ} \mathrm{C}$. At what temperature is the partial pressure of this substance 1180 torr?

1. $-7.92^{\circ} \mathrm{C}$
2. $181^{\circ} \mathrm{C}$
3. $-381^{\circ} \mathrm{C}$
4. $176^{\circ} \mathrm{C}$
5. $150^{\circ} \mathrm{C}$ correct
6. $-281^{\circ} \mathrm{C}$
7. $162^{\circ} \mathrm{C}$

## Explanation:

Here we use the Clausius-Clapeyron equation to solve for $T_{1}$ :

$$
\ln \left(\frac{P_{2}}{P_{1}}\right)=\frac{\Delta H_{\mathrm{vap}}}{R}\left(\frac{1}{T_{1}}-\frac{1}{T_{2}}\right)
$$

$P_{1}=1180$ torr
$P_{2}=760$ torr
$T_{2}=124^{\circ} \mathrm{C}+273=401 \mathrm{~K}$
$\Delta H_{\text {vap }}=28.4 \mathrm{~kJ} / \mathrm{mol}$
$R=0.008314 \mathrm{~kJ} / \mathrm{mol} \mathrm{K}$
And...
$T_{1}=150^{\circ} \mathrm{C}$
$007 \quad 10.0$ points
A sample of 44.1 g of para-dichlorobenzene $\left(\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Cl}_{2} 147.0 \mathrm{~g} / \mathrm{mol}\right)$ is dissolved into 350 mL of hexane $\left(\mathrm{C}_{6} \mathrm{H}_{14}, 86.18 \mathrm{~g} / \mathrm{mol}\right.$, density $0.661 \mathrm{~g} / \mathrm{mL})$. What is the molality of this solution?

1. 1.30 m correct
2. 0.567 m
3. 0.101 m
4. 1.17 m
5. 0.857 m

## Explanation:

Molality is defined as the moles of solute divided by kg solvent. Solve first for the mass
of solvent:

$$
350 \mathrm{~mL} \times \frac{0.661 \mathrm{~g}}{\mathrm{~mL}}=231.35 \mathrm{~g}
$$

mol of solute $=44.1 / 147=0.300 \mathrm{~mol}$ solute Next take the ratio of moles solute per kg solvent:

$$
\frac{0.300 \mathrm{~mol}}{0.23135 \mathrm{~kg}}=1.2967=1.30 \mathrm{~m}
$$

## $008 \quad 10.0$ points

$A$ and $B$ are mildly volatile solvents. A mixture is made by combining 2 moles of A with 3 moles of B. Interpret the diagram below to determine the vapor pressure of this mixture.

1. 80 Torr
2. 70 Torr
3. 100 Torr
4. 120 Torr correct
5. 140 Torr
6. 130 Torr
7. 110 Torr
8. 150 Torr
9. 90 Torr

## Explanation:

Mixing 2 mol A and 3 mol B is a $2 / 5 \mathrm{~mol}$ fraction of $A$, or 0.4 . Each vertical grid line is 0.1 mol fraction units, so counting 4 over we have the right line. Following it all the way up to the mixture vapor pressure we get 120 Torr (see diagram below). Alternatively, you can
use Raoult's Law and Dalton's law to take the sum of partial pressures, which is simply 120 torr $=0.4(60)+0.6(160)$

$009 \quad 10.0$ points
Calculate the number of moles of oxygen that will dissolve in 45 L of water at $20^{\circ} \mathrm{C}$ if the partial pressure of oxygen is 0.21 atm . The Henry's Law constant for oxygen in water at $20^{\circ} \mathrm{C}$ is $0.0013 \mathrm{M} / \mathrm{atm}$.

1. 0.0013 mol
2. 0.00027 mol
3. 0.28 mol
4. 0.012 mol correct
5. 0.0062 mol

## Explanation:

## $010 \quad 10.0$ points

A 19.7 g sample of an unknown salt (formula $=\mathrm{MX}_{2}$ ) is dissolved in 249.4 mL water. The boiling point of water in this solution is $100.657^{\circ} \mathrm{C}$. What is the molecular weight of the unknown salt?

1. $129.8 \mathrm{~g} / \mathrm{mol}$
2. $55.4 \mathrm{~g} / \mathrm{mol}$
3. $46.1 \mathrm{~g} / \mathrm{mol}$
4. $185 \mathrm{~g} / \mathrm{mol}$ correct
5. $61.6 \mathrm{~g} / \mathrm{mol}$

## Explanation:

Using the equation $\Delta T=i \cdot k_{b} \cdot m$, you can
solve for the molality of the unknown salt in water.

$$
\begin{gathered}
m=\frac{0.657}{3 \cdot 0.512} \\
m=0.4277 \mathrm{~mol} \mathrm{~kg}^{-1}
\end{gathered}
$$

Then convert molality into moles by multiplying by the mass of the $\mathrm{H}_{2} \mathrm{O}$ solvent:

$$
\frac{0.4277 \mathrm{~mol}}{\mathrm{~kg}}\left(\frac{0.2494 \mathrm{~kg}}{1}\right)=0.1067 \mathrm{~mol}
$$

Finally, we can use the gram quantity and number of moles to solve for the molecular weight of the salt:

$$
\frac{19.7 \mathrm{~g}}{0.1067 \mathrm{~mol}}=185 \mathrm{~g} / \mathrm{mol}
$$

## $011 \quad 10.0$ points

Isocarboxazid ( $\mathrm{MW}=231.25 \mathrm{~g} / \mathrm{mol}$ ) is an organic monoamine oxidase inhibitor used to treat depression disorders. 38.00 grams of isocarboxazid are added to water to make a 350 mL aqueous solution. What is the osmotic pressure exerted by this solution across a semi-permeable membrane at $37^{\circ} \mathrm{C}$ ?

1. 12.10 atm
2. 329.6 atm
3. 11.95 atm correct
4. 1.43 atm
5. 144.4 atm
6. 23.90 atm

## Explanation:

Osmotic pressure is calculated using the formula:

$$
\Pi=M R T
$$

$R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{mol} \cdot \mathrm{K}$
$T=310.15 \mathrm{~K}$
Solving first for molarity:

$$
M=\frac{(38.0 \mathrm{~g})\left(\frac{\mathrm{mol}}{231.25 \mathrm{~g}}\right)}{0.350 \mathrm{~L}}=0.4695 \mathrm{M}
$$

$11.95 \mathrm{~atm}=(0.4695)(0.08206)(310.15)$

## $012 \quad 10.0$ points

Write the equilibrium constant for the following reaction.

$$
\mathrm{H}_{2}(\mathrm{~g})+\mathrm{Br}_{2}(\ell) \rightleftharpoons 2 \mathrm{HBr}(\mathrm{~g})
$$

1. $K_{p}=\frac{P_{\mathrm{HBr}}}{P_{\mathrm{H}_{2}}}$
2. $K_{p}=\frac{P_{\mathrm{HBr}}^{2}}{P_{\mathrm{H}_{2}} P_{\mathrm{Br}_{2}}}$
3. $K_{p}=\frac{P_{\mathrm{H}_{2}}}{P_{\mathrm{HBr}}^{2}}$
4. $K_{p}=\frac{P_{\mathrm{HBr}}^{2}}{P_{\mathrm{H}_{2}}\left[\mathrm{Br}_{2}\right]}$
5. $K_{p}=\frac{P_{\mathrm{HBr}}^{2}}{P_{\mathrm{H}_{2}}}$

## correct

## Explanation:

Take the concentration of the products raised to the power of their coefficients divided by the reactants raised to the power of their coefficients, ignoring any liquid or solids.

$$
K_{p}=\frac{\mathrm{P}_{\mathrm{HBr}}^{2}}{\mathrm{P}_{\mathrm{H}_{2}}}
$$

## $013 \quad 10.0$ points

Consider the following generic gas phase reaction.

$$
\mathrm{X}_{2}(\mathrm{~g})+3 \mathrm{Y}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{XY}_{3}(\mathrm{~g})
$$

The value of $K_{\mathrm{p}}$ for this reaction is 107 . Calculate the equilibrium partial pressure of gas $\mathrm{Y}_{2}$ if the equilibrium partial pressures of $\mathrm{XY}_{3}$ is 0.50 atm and $\mathrm{X}_{2}$ is 0.15 atm ?

1. 5.6 atm
2. 0.25 atm correct
3. 0.016 atm
4. 0.42 atm
5. 0.33 atm
6. 0.031 atm
7. 0.18 atm

## Explanation:

$107=K_{\mathrm{p}}$
$107=\frac{\left(P_{\mathrm{XY}_{3}}\right)^{2}}{\left(P_{\mathrm{X}_{2}}\right)\left(P_{\mathrm{Y}_{2}}\right)^{3}}=\frac{(0.50)^{2}}{(0.15)\left(P_{\mathrm{Y}_{2}}\right)^{3}}$
$\mathrm{P}_{\mathrm{Y}_{2}}=0.25 \mathrm{~atm}$

## $014 \quad 10.0$ points

$0.834 \mathrm{~atm} \mathrm{~A}, 0.565 \mathrm{~atm} \mathrm{~B}$, and 1.24 atm C are placed into a container to run the following reaction:

$$
2 \mathrm{~A}(\mathrm{~g})+\mathrm{B}(\mathrm{~g}) \rightleftharpoons 3 \mathrm{C}(\mathrm{~g})
$$

At equilibrium, 0.435 atm C remains. What is $K_{p}$ for this reaction?

1. 0.0526 correct
2. 0.107
3. 0.0230
4. 8.12
5. 18.8

## Explanation:

The first thing to observe in this question is that the reaction runs in reverse, because C is consumed over the course of the reaction. Running a RICE table, you will see that the change in C is equal to $-3 x=0.435-1.24=$ -0.805 ; therefore, $x=0.2683$.

$$
\begin{aligned}
& P_{\mathrm{A}}=0.834+2 x=1.37067 \\
& P_{\mathrm{B}}=0.565+x=.83333
\end{aligned}
$$

Now you can solve for the equilibrium constant, $K_{p}$ :

$$
K_{p}=\frac{0.435^{3}}{1.37067^{2} \cdot .83333}=0.05258
$$

Consider the following reaction for the next two questions:

$$
\mathrm{CO}(\mathrm{~g})+2 \mathrm{H}_{2}(\mathrm{~g}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{OH}(\mathrm{~g})
$$

Beginning at equilibrium, which of the following will result in a shift toward the right of this reaction?

## 1. Adding $\mathrm{CH}_{3} \mathrm{OH}$ gas

2. Adding an inert gas at constant pressure
3. Adding an inert gas at constant volume
4. Removing CO gas
5. Reducing the volume of the container correct

## Explanation:

The only option that will cause a shift to the right of this reaction is reducing the volume of the container. By reducing the volume of the container, the pressure is increased. Increasing the overall pressure results in a shift way from the side of the reaction with the most gas moles.

016 (part 2 of 2) 10.0 points
If this reaction is exothermic, lowering the temperature will cause the reaction to...

1. shift right due to a decreased $Q$ value
2. shift left due to a smaller $K$ value
3. shift left due to a smaller $Q$ value
4. shift right due to a larger $K$ value correct
5. remain at equilibrium

## Explanation:

Reducing the temperature of an exothermic reaction will cause the reaction to shift to the right. This is because an exothermic reaction will have a larger $K$ value when the temperature is decreased.

## $017 \quad 10.0$ points

Calculate the pH of a $0.018 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}$ solution.

1. 8.44
2. 12.26
3. 12.56 correct
4. 5.26
5. 1.44
6. 1.74

## Explanation:

$0.018 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}$ is a strong base that dissociates completely, resulting in a 0.036 M hydroxide ion concentration.

$$
\begin{gathered}
\mathrm{pOH}=-\log (0.036 \mathrm{M}) \\
\mathrm{pH}=14-\mathrm{pOH}=12.56
\end{gathered}
$$

## $018 \quad 10.0$ points

What is the pH of a 0.12 M solution of hydroxylammonium bromide $\left(\mathrm{NH}_{3} \mathrm{OHBr}\right)$ ?

1. 9.56
2. 3.72
3. 3.24
4. 3.61
5. 3.33
6. 4.44
7. 6.04

## 8. 3.48 correct

## Explanation:

$M_{\mathrm{NH}_{3} \mathrm{OHBr}}=0.12 \mathrm{M} \quad K_{\mathrm{b}}=1.1 \times 10^{-8}$
It's a salt of a weak base (BHX). This means you need a $K_{\mathrm{a}}$ for the weak acid $\mathrm{BH}^{+}$. Use $K_{\mathrm{a}}=\frac{K_{\mathrm{w}}}{K_{\mathrm{b}}}$ and you'll get the $K_{\mathrm{a}}=9.09091 \times$
$10^{-7}$. You CAN use the approximation for the equilibrium which means that

$$
\begin{aligned}
{\left[\mathrm{H}^{+}\right] } & =\sqrt{K_{\mathrm{a}} \cdot C_{\mathrm{BH}^{+}}}=0.000330289 \mathrm{M} \\
\mathrm{pH} & =-\log (0.000330289)=3.48111
\end{aligned}
$$

## $019 \quad 10.0$ points

Rank the following acids in increasing order of acidity.
$\mathrm{HCN} \quad \mathrm{NH}_{3} \mathrm{OH}^{+} \quad \mathrm{HNO}_{2} \quad \mathrm{HBrO}$

1. $\mathrm{NH}_{3} \mathrm{OH}^{+}<\mathrm{HNO}_{2}<\mathrm{HBrO}<\mathrm{HCN}$
2. $\mathrm{NH}_{3} \mathrm{OH}^{+}<\mathrm{HBrO}<\mathrm{HCN}<\mathrm{HNO}_{2}$
3. $\mathrm{HCN}<\mathrm{NH}_{3} \mathrm{OH}^{+}<\mathrm{HNO}_{2}<\mathrm{HBrO}$
4. $\mathrm{HCN}<\mathrm{HBrO}<\mathrm{NH}_{3} \mathrm{OH}^{+}<\mathrm{HNO}_{2}$ correct
5. $\mathrm{HNO}_{2}<\mathrm{NH}_{3} \mathrm{OH}^{+}<\mathrm{HBrO}<\mathrm{HCN}$
6. $\mathrm{HNO}_{2}<\mathrm{HBrO}<\mathrm{HCN}<\mathrm{NH}_{3} \mathrm{OH}^{+}$

## Explanation:

Look at the coversheet for the values of $\mathrm{p} K_{\mathrm{a}}$.
$\mathrm{HCN}=9.21$
$\mathrm{NH}_{3} \mathrm{OH}^{+}=14-7.96=6.04$
$\mathrm{HNO}_{2}=3.40$
$\mathrm{HBrO}=8.20$
$\mathrm{HCN}<\mathrm{HBrO}<\mathrm{NH}_{3} \mathrm{OH}^{+}<\mathrm{HNO}_{2}$

## $020 \quad 10.0$ points

A weak acid, HA, ionizes $7.65 \%$ at a 0.250 M concentration. What is the hydroxide ion concentration in this solution?

1. $1.91 \times 10^{-16} \mathrm{M}$
2. $1.31 \times 10^{-13} \mathrm{M}$
3. $1.00 \times 10^{-14} \mathrm{M}$
4. $5.23 \times 10^{-13} \mathrm{M}$ correct
5. $1.91 \times 10^{-2} \mathrm{M}$

## Explanation:

Percent ionization quickly gives you the dissociation of a weak electrolyte at a particular concentration:

$$
\begin{gathered}
{\left[\mathrm{H}^{+}\right]=0.0765 \times 0.25 \mathrm{M}} \\
{\left[\mathrm{H}^{+}\right]=0.019125 \mathrm{M}}
\end{gathered}
$$

Use $K_{\mathrm{w}}$ to convert this into $\left[\mathrm{OH}^{-}\right]$:

$$
\left[\mathrm{OH}^{-}\right]=\frac{1 \times 10^{-14}}{0.019125 \mathrm{M}}
$$

$$
\left[\mathrm{OH}^{-}\right]=5.23 \times 10^{-13} \mathrm{M}
$$

## $021 \quad 10.0$ points

What is the pH after 250 mL of 0.25 M $\mathrm{HNO}_{3}$ is added to 350 mL of $0.50 \mathrm{M} \mathrm{CH}_{3} \mathrm{NH}_{2}$ (methylamine) ?

1. 10.90 correct
2. 6.21
3. 5.05
4. 3.36
5. 10.64
6. 10.38
7. 3.62
8. 2.29

## Explanation:

This is a simple Henderson-Hasselbach calculation.

$$
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{C_{\mathrm{B}}}{C_{\mathrm{BH}^{+}}}\right)
$$

The $\mathrm{p} K_{\mathrm{b}}$ for methylamine (the base, B ) is 3.36 which means the $\mathrm{p} K_{\mathrm{a}}$ for the methylammonium ion $\left(\mathrm{BH}^{+}\right)$is 10.64 . You may use the ratio of moles because this is a partial neutralization (buffer) problem. The weak base methylamine, B , is converted to the conjugate acid, $\mathrm{BH}^{+}$via the reaction with the strong acid.

$$
\mathrm{B}+\mathrm{H}^{+} \rightarrow \mathrm{BH}^{+}
$$

The acid is the limiting reactant and determines the amount of $\mathrm{BH}^{+}$made. Remember, volume times concentration equals amount (moles).
$\mathrm{mol} \mathrm{BH}+=0.25(0.250)=0.0625 \mathrm{~mol}$
$\mathrm{mol} \mathrm{B}=.50(0.350)-0.0625 \mathrm{~mol}=.1125 \mathrm{~mol}$
Now solve for pH using the $\mathrm{H}-\mathrm{H}$ equation:

$$
\begin{aligned}
\mathrm{pH} & =10.64+\log \left(\frac{0.1125}{0.0625}\right) \\
\mathrm{pH} & =10.64+0.26 \\
\mathrm{pH} & =10.90
\end{aligned}
$$

## $022 \quad 10.0$ points

What is the ratio of potassium acetate to acetic acid necessary to make a buffer with a pH equal to 5.12 ?

1. 3.1

## 2. 2.4 correct

3. 0.38
4. 9.86
5. 0.42
6. 2.9

## Explanation:

You can solve for the ratio using the $\mathrm{H}-\mathrm{H}$ equation and knowledge of $\log$ rules:

$$
\begin{aligned}
& \mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}\right) \\
& 5.12=4.74+\log \left(\frac{\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}\right) \\
& 10^{5.12-4.74}=\frac{\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}
\end{aligned}
$$

$$
=2.4
$$

## $023 \quad 10.0$ points

What is the dominant species in solution at the equivalence point of a weak base-strong
acid titration?

1. Strong base
2. Equal parts weak acid and weak base
3. Weak acid correct
4. Neutral salt
5. Weak base
6. Strong acid

## Explanation:

The dominant species in solution at the equivalence point will be the conjugate of the analyte. In this case, the dominant species in solution will be the conjugate of the weak base, which is just a weak acid.

024 (part 1 of 3 ) 10.0 points
A sample of 30 mL of a weak acid (HA) solution was titrated with 0.075 M NaOH . The pH curve for this titration is shown.

What is the concentration of the original weak acid solution (the 30 mL )?

1. 0.032 M
2. 0.022 M
3. 0.055 M correct
4. 0.075 M
5. 0.048 M

## Explanation:

equivalence point is 22 mL of NaOH $\times 0.075 \mathrm{M}=1.65 \mathrm{mmol} \mathrm{OH}-$
mmol acid $=\mathrm{mmol}$ base
$1.65 \mathrm{mmol} / 30 \mathrm{~mL}=0.055 \mathrm{M} \mathrm{HA}$
025 (part 2 of 3 ) 10.0 points
Which of the following is the value of $K_{\mathrm{a}}$ for the weak acid, HA ?

1. $1.3 \times 10^{-6}$
2. $5.0 \times 10^{-7}$ correct
3. $3.2 \times 10^{-10}$
4. $1.2 \times 10^{-7}$
5. $7.6 \times 10^{-5}$

## Explanation:

The half titration point is at 11 mL and the $\mathrm{pH}=\mathrm{pKa}$ there which is 6.3 . That would match a $K_{\mathrm{a}}$ of $5.0 \times 10^{-7}$.

## 026 (part 3 of 3 ) 10.0 points

Below is a listing of five indicators and their associated $\mathrm{p} K_{\mathrm{a}}$ values. Which indicator would be the best one to use for this titration?

1. methyl red, 5.0
2. bromophenol blue, 4.1
3. bromocresol purple, 6.4
4. phenol red, 7.4
5. thymol blue, 9.3 correct
6. alizarin yellow, 10.9

## Explanation:

The equivalence point is at a pH of 9.5 . Only thymol blue in this listing covers that pH during the color transition.

## $027 \quad 10.0$ points

Which of the following salts is the most soluble in pure water?

1. $\mathrm{BaSO}_{4} \quad K_{\mathrm{sp}}=1.1 \times 10^{-10}$
2. $\mathrm{CuBr} \quad K_{\mathrm{sp}}=6.3 \times 10^{-9}$
3. All of these salts have the same solubility
4. $\mathrm{CaF}_{2} \quad K_{\text {sp }}=3.5 \times 10^{-11}$ correct

## Explanation:

Calculate the molar solubility, $x$, for each substance:

$$
\begin{aligned}
& \mathrm{CaF}_{2}: \quad K_{\mathrm{sp}}=3.5 \times 10^{-11}=4 x^{3} \\
& x=2.06 \times 10^{-4}(\text { correct }) \\
& \mathrm{BaSO}_{4}: \quad K_{\mathrm{sp}}=1.1 \times 10^{-10}=x^{2} \\
& x=1.05 \times 10^{-5} \\
& \mathrm{CuBr}: \quad K_{\mathrm{sp}}=6.3 \times 10^{-9}=x^{2} \\
& x=7.94 \times 10^{-5}
\end{aligned}
$$

## $028 \quad 10.0$ points

Barium fluoride $\left(\mathrm{BaF}_{2}\right)$ is most soluble in which of the following solutions?

1. $0.15 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}$
2. 0.50 M NaF
3. 0.18 M NaF
4. $0.005 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}$ correct
5. The molar solubility of barium fluoride is the same in each of these solutions

## Explanation:

According to the common ion effect, solubility decreases as the effective concentration of a common ion increases. The smallest common ion concentration would be the 0.005 M $\mathrm{Ba}(\mathrm{OH})_{2}$.

## $029 \quad 10.0$ points

You mix $0.02 \mathrm{mmol} \operatorname{Sr}\left(\mathrm{NO}_{3}\right)_{2}$ solution and 0.05 mmol NaF solution to form a 100 mL solution. What precipitate (if any) forms?

## 1. NaF

2. $\mathrm{SrF}_{2}$
3. No precipitate forms correct
4. $\mathrm{Sr}\left(\mathrm{NO}_{3}\right)_{2}$

## 5. $\mathrm{NaNO}_{3}$

## Explanation:

First, come up with the double-displacement equation for this problem to show that $\mathrm{SrF}_{2}$ is the solid product. However, this product will only be formed if $Q>K$. Therefore, you must solve for $Q_{\mathrm{sp}}$ at the instant of mixing:

$$
\begin{gathered}
Q_{\mathrm{sp}}=\left[\mathrm{Sr}^{2+}\right]\left[\mathrm{F}^{-}\right]^{2} \\
Q_{\mathrm{sp}}=(.0002)(0.0005)^{2}=5.11 \times 10^{-11}
\end{gathered}
$$

Compare to $K_{\mathrm{sp}}$, which is $4.3 \times 10^{-9}$. Because $Q$ is less than $K$, the solution is understaturated and no precipitate forms.

## $030 \quad 10.0$ points

What is the mass of the barium chromate precipitate resulting from the addition of 300 $\mathrm{mL} 0.025 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}$ to 200 mL 0.040 M $\mathrm{Na}_{2} \mathrm{CrO}_{4}$ ?

1. 3.48 g
2. 2.03 g
3. 1.90 g correct
4. 3.80 g
5. 2.52 g

## Explanation:

Start with the relevant net ionic formula based on what was provided in the question stem (Note: you can confirm that a precipitate will form using $Q_{\mathrm{sp}}$ ):

$$
\mathrm{Ba}^{2+}(\mathrm{aq})+\mathrm{CrO}_{4}^{2-}(\mathrm{aq}) \longrightarrow \mathrm{BaCrO}_{4}(\mathrm{~s})
$$

Here you should see that this is a limiting reagent problem. Because barium chromate has a very small $K_{\text {sp }}$, it is safe to assume the reaction goes approximately $100 \%$. Solve for moles of each reagent:

$$
\mathrm{Ba}^{2+}: 0.0250 \mathrm{M} \times 0.300 \mathrm{~L}=0.00750 \mathrm{~mol}
$$

$$
\mathrm{CrO}_{4}^{2-}: 0.0400 \mathrm{M} \times 0.200 \mathrm{~L}=0.00800 \mathrm{~mol}
$$

This reaction is $1: 1: 1$, so you can determine that the limiting reagent is the reactant with the fewest number of moles. This is also the number of moles of product formed. Convert to mass:

$$
0.00750 \times 253.37 \mathrm{~g} / \mathrm{mol}=1.90 \mathrm{~g}
$$

## $031 \quad 10.0$ points

Consider the following reaction:

$$
2 \mathrm{C}_{2} \mathrm{H}_{6}(\mathrm{~g})+7 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 4 \mathrm{CO}_{2}(\mathrm{~g})+6 \mathrm{H}_{2} \mathrm{O}(\ell)
$$

Oxygen is being consumed at a rate equal to $1.24 \mathrm{M} / \mathrm{s}$. What is the initial rate at which carbon dioxide is forming?

1. $4.96 \mathrm{M} / \mathrm{s}$
2. $8.68 \mathrm{M} / \mathrm{s}$
3. $2.17 \mathrm{M} / \mathrm{s}$
4. $1.24 \mathrm{M} / \mathrm{s}$
5. $0.709 \mathrm{M} / \mathrm{s}$ correct

## Explanation:

The stoichiometric ration between carbon dioxide and oxygen is $4: 7$. This means that carbon dioxide is being formed at $\frac{4}{7}$ the initial rate of oxygen.

$$
1.24 \mathrm{M} / \mathrm{s} \times \frac{4 \mathrm{CO}_{2}}{7 \mathrm{O}_{2}}=0.709 \mathrm{M} / \mathrm{s}
$$

032 (part 1 of 2) $\mathbf{1 0 . 0}$ points
You run an experiment to determine the initial rates of the following generic reaction at various starting conditions:

$$
\mathrm{A}+\mathrm{X}_{2} \rightleftharpoons \mathrm{AX}_{2}
$$

|  | $[\mathrm{A}]$ | $\left[\mathrm{X}_{2}\right]$ | initial rate |
| :--- | :---: | :---: | :---: |
|  | M | M | $\mathrm{M} \cdot \mathrm{s}^{-1}$ |
| Trial 1 | 0.60 | 1.56 | $2.00 \times 10^{-3}$ |
| Trial 2 | 0.60 | 3.12 | $8.00 \times 10^{-3}$ |
| Trial 3 | 1.20 | 1.56 | $4.00 \times 10^{-3}$ |
| Trial 4 | 0.90 | 2.40 | $7.10 \times 10^{-3}$ |

What is the correct rate law for the reaction?

1. Rate $=(1.40)[\mathrm{A}]$
2. Rate $=\left(3.84 \times 10^{-3}\right)[\mathrm{A}]^{-1}\left[\mathrm{X}_{2}\right]^{2}$
3. Rate $=\left(3.84 \times 10^{-3}\right)[\mathrm{A}]\left[\mathrm{X}_{2}\right]^{2}$
4. Rate $=\left(1.37 \times 10^{-3}\right)[\mathrm{A}]\left[\mathrm{X}_{2}\right]$
5. Rate $=\left(1.37 \times 10^{-3}\right)[\mathrm{A}]\left[\mathrm{X}_{2}\right]^{2}$ correct

## Explanation:

Begin with the equation:

$$
\text { Rate }=k[\mathrm{~A}]^{x}[\mathrm{~B}]^{y}
$$

Compare trials to determine the value of $x$ and $y$. Two good comparisons are trials 1 and 2 and trials 1 and 3.

Between trials 1 and 2, the concentration of $\mathrm{X}_{2}$ doubles and the rate quadruples. Therefore, $y=2$, meaning the reaction is second order in $\mathrm{X}_{2}$.

Between trials 1 and 3, [A] doubles and the rate doubles. This means $x=1$ and the reaction is first order in A.

Lastly, you can solve for $k$ using any trial:

$$
2.00 \times 10^{-3}=\left(1.37 \times 10^{-3}\right)(0.60)(1.56)^{2}
$$

033 (part 2 of 2) $\mathbf{1 0 . 0}$ points
What are the units of the rate constant in the previous question?

1. $\frac{1}{\mathrm{M}^{2} \cdot \mathrm{~S}}$ correct
2. $\frac{1}{\mathrm{M}^{3} \cdot \mathrm{~s}}$
3. $\frac{1}{\mathrm{M}^{4} \cdot \mathrm{~S}}$
4. $\frac{1}{\mathrm{M} \cdot \mathrm{s}}$
5. $\frac{\mathrm{M}}{\mathrm{S}}$

## Explanation:

The rate constant has units that cancel out the concentrations in the rate law to give a rate in $\mathrm{M} / \mathrm{s}$. The rate constant has units of $\frac{1}{\mathrm{M}^{2} \cdot \mathrm{~S}}$

## $034 \quad 10.0$ points

The chlorination of methane is an exothermic reaction with a two-step mechanism shown below:

Step 1: $\mathrm{CH}_{4}+\mathrm{Cl}_{2} \longrightarrow \mathrm{CH}_{3}+\mathrm{HCl}$ (slow)
Step 2: $\mathrm{CH}_{3}+\mathrm{Cl}_{2} \longrightarrow \mathrm{CH}_{3} \mathrm{Cl}+\mathrm{Cl}^{-}$(fast)
Which of the following reaction coordinate diagrams best fits this data?
1.

2.

3.

4.

5.

6.

## Explanation:

The reaction coordinate diagram should match the mechanism and thermodynamics of the reaction. The reaction profile is exothermic, has two humps, and the first hump should be the largest (rate-determining step).

## $035 \quad 10.0$ points

Consider the following overall reaction:

$$
2 \mathrm{~A}_{2}+\mathrm{X} \rightarrow \mathrm{~B}
$$

Using the overall reaction, determine the rate law for the following mechanism:

$$
\begin{array}{lr}
\mathrm{A}_{2}+\mathrm{X} \rightleftharpoons \mathrm{Z}+\mathrm{Y} & \left(k_{1}, \text { fast }\right) \\
\mathrm{Z}+\mathrm{Y} \rightarrow \mathrm{I} & \left(k_{2}, \text { slow }\right) \\
\mathrm{I}+\mathrm{A}_{2} \rightarrow \mathrm{~B} & \left(k_{3}, \text { fast }\right)
\end{array}
$$

1. Rate $=k^{\prime}[\mathrm{Z}][\mathrm{Y}]$
2. Rate $=k^{\prime}\left[\mathrm{A}_{2}\right][\mathrm{X}]$ correct
3. Rate $=k^{\prime}\left[\mathrm{A}_{2}\right]^{2}[\mathrm{X}]$
4. Rate $=k^{\prime}[\mathrm{Z}][\mathrm{X}]$
5. Rate $=k^{\prime}\left[\mathrm{A}_{2}\right]^{2}$
6. Rate $=k^{\prime}\left[\mathrm{A}_{2}\right][\mathrm{Z}][\mathrm{X}]$

## Explanation:

The slowest step is the rate determining step and is used to write the rate law:

$$
\text { Rate }=k_{2}[\mathrm{Z}][\mathrm{Y}]
$$

For the final answer, we need the rate law in terms of only the reactants of the overall reaction. We need to substitute in for [Z] using the previous fast step in equilibrium:

$$
\begin{gathered}
k_{1}\left[\mathrm{~A}_{2}\right][\mathrm{X}]=k_{-1}[\mathrm{Z}][\mathrm{Y}] \\
{[\mathrm{Z}]=\frac{k_{1}}{k_{-1}} \frac{\left[\mathrm{~A}_{2}\right][\mathrm{X}]}{[\mathrm{Y}]}}
\end{gathered}
$$

If you fit this into your original rate law, you will see that $[\mathrm{Y}]$ cancels out:

$$
\text { Rate }=\frac{k_{2} k_{1}}{k_{-1}} \frac{\left[\mathrm{~A}_{2}\right][\mathrm{X}][\mathrm{Y}]}{[\mathrm{Y}]}
$$

So our final answer is just:

$$
\text { Rate }=k^{\prime}\left[\mathrm{A}_{2}\right][\mathrm{X}]
$$

## $036 \quad 10.0$ points

How does a catalyst affect the rate of a chemical reaction?

1. A catalyst increases the energy of the transition state such that a larger number of particles have sufficient energy to overcome the activation energy
2. A catalyst increases the rate constant by providing an alternate mechanism with a lower activation energy correct
3. A catalyst increases the rate constant by increasing the activation energy
4. A catalyst decreases the rate constant by lowering the activation energy

## Explanation:

A catalyst increases the rate constant by providing an alternate mechanism with a lower activation energy

## $037 \quad 10.0$ points

${ }_{42}^{99}$ Mo undergoes radioactive decay by emitting a single beta particle. Which of the following reactions corresponds to this process?

1. ${ }_{42}^{99} \mathrm{Mo} \longrightarrow{ }_{42}^{98} \mathrm{Tc}+{ }_{0}^{1} n$
2. ${ }_{42}^{99} \mathrm{Mo} \longrightarrow{ }_{43}^{99} \mathrm{Tc}+{ }_{-1}^{0} \beta$ correct
3. ${ }_{42}^{99} \mathrm{Mo}+{ }_{-1}^{0} \beta \longrightarrow{ }_{41}^{99} \mathrm{Nb}$
4. ${ }_{42}^{99} \mathrm{Mo}+{ }_{-1}^{0} \beta \longrightarrow{ }_{43}^{99} \mathrm{Tc}$
5. ${ }_{42}^{99} \mathrm{Mo} \longrightarrow{ }_{44}^{99} \mathrm{Ru}+{ }_{-1}^{0} \beta$

## Explanation:

Write the balanced reaction involving the emission of a ${ }_{-1}^{0} \beta$ particle.
${ }_{42}^{99} \mathrm{Mo} \longrightarrow{ }_{43}^{99} \mathrm{Tc}+{ }_{-1}^{0} \beta$
$038 \quad 10.0$ points
Identify the missing isotope in the nuclear reaction.

$$
{ }_{88}^{226} \mathrm{Ra} \rightarrow \quad ?+{ }_{2}^{4} \alpha
$$

1. ${ }_{86}^{230} \mathrm{Th}$
2. ${ }_{90}^{230} \mathrm{Th}$
3. ${ }_{90}^{222} \mathrm{Rn}$
4. ${ }_{86}^{222} \mathrm{Rn}$ correct
5. ${ }_{86}^{226} \mathrm{Rn}$

## Explanation:

$$
{ }_{88}^{226} \mathrm{Ra} \rightarrow{ }_{86}^{222} \mathrm{Rn}+{ }_{2}^{4} \alpha
$$

## $039 \quad 10.0$ points

${ }^{123} \mathrm{I}$ is a radioactive isotope $\left(t_{1 / 2}=13.22\right.$ hours) useful for clinical imaging. How long will it take for a dose to diminish to $18.7 \%$ of its original value?

1. 22.2 hours
2. 38.7 hours
3. 557 hours
4. 29.7 hours
5. 87.9 hours
6. 34.2 hours
7. 70.7 hours

## 8. 32.0 hours correct

## Explanation:

This is radioactive decay, meaning we must follow first-order kinetics:

$$
\ln \left(\frac{100}{18.7}\right)=k t
$$

Solve for $k$ first:

$$
\begin{aligned}
k & =\frac{\ln (2)}{13.22 \text { hours }} \\
k & =0.052431708 \text { hours }^{-1}
\end{aligned}
$$

Now complete the equation up top to solve for t :
$\ln \left(\frac{100}{18.7}\right) / 0.052431708$ hours $^{-1}=t$
$t=32.0$ hours

## $040 \quad 10.0$ points

When direct heat is applied to potassium chlorate, $\mathrm{KClO}_{3}$, it decomposes to form KCl and other byproducts. Was chlorine oxidized or reduced? How many electrons were transferred during the process?

1. oxidized, 6 electrons
2. oxidized, 4 electrons
3. reduced, 9 electrons
4. reduced, 3 electrons
5. reduced, 6 electrons correct
6. oxidized, 3 electrons

## Explanation:

For the conversion of $\mathrm{KClO}_{3}$ to KCl , the Cl atom is going from $\mathrm{a}+5$ to a -1 oxidation state. This is a reduction reaction that involves the gain of 6 electrons.

The following reaction occurs in acidic conditions. What is the coefficient of water in the overall balanced equation? Is it a reactant or a product?

$$
\mathrm{As}_{2} \mathrm{O}_{3}+\mathrm{NO}_{3}^{-} \longrightarrow \mathrm{H}_{3} \mathrm{AsO}_{4}+\mathrm{NO}
$$

1. 7 ; reactant correct
2. 3; product
3. 2; product
4. 2; reactant
5. 4; reactant
6. 3; reactant

## Explanation:

The correctly balanced equation is:

$$
\begin{aligned}
7 \mathrm{H}_{2} \mathrm{O}+4 \mathrm{H}^{+}+3 \mathrm{As}_{2} \mathrm{O}_{3} & +4 \mathrm{NO}_{3}^{-} \\
& 6 \mathrm{H}_{3} \mathrm{AsO}_{4}+4 \mathrm{NO}
\end{aligned}
$$

042 (part 1 of 2) 10.0 points
What is the shorthand notation for the following electrochemical cell?
$2 \mathrm{Cr}^{2+}(\mathrm{aq})+\mathrm{Co}^{2+}(\mathrm{aq}) \longrightarrow 2 \mathrm{Cr}^{3+}(\mathrm{aq})+\mathrm{Co}(\mathrm{s})$

1. $\mathrm{Pt}\left|\mathrm{Cr}^{2+}, \mathrm{Cr}^{3+} \| \mathrm{Co}^{2+}\right|$ Co correct
2. $\mathrm{Cr}^{2+}, \mathrm{Cr}^{3+} \| \mathrm{Co}^{2+} \mid \mathrm{Co}$
3. $\mathrm{Co}\left|\mathrm{Co}^{2+} \| \mathrm{Cr}^{2+}, \mathrm{Cr}^{3+}\right| \mathrm{Pt}$
4. $\mathrm{Co}^{2+} \mid \mathrm{Co} \| \mathrm{Cr}^{2+}, \mathrm{Cr}^{3+}$
5. $\mathrm{Cr}^{2+}\left|\mathrm{Cr}^{3+} \| \mathrm{Co}^{2+}\right| \mathrm{Co}$

## Explanation:

You must use an inert electrode in the chromium solution compartment because you do not have a solid metal anode. Otherwise, follow your convention of: anode - anodic so-lution- cathodic solution - cathode

043 (part 2 of 2) $\mathbf{1 0 . 0}$ points
What is the oxidizing agent in the previous problem?

1. Co
2. Pt
3. $\mathrm{Cr}^{2+}$
4. $\mathrm{Co}^{2+}$ correct
5. $\mathrm{Cr}^{3+}$

## Explanation:

The oxidizing agent is the species being reduced. This is $\mathrm{Co}^{2+}$.

## 044 (part 1 of 2) 10.0 points

The following two questions refer to this diagram for a voltaic cell. Neither of the two electrodes are an inert electrode.

Where would you find the species that is being oxidized?

1. E
2. C
3. B
4. D

## 5. A correct

## Explanation:

A is the electrode in the anode cell. Oxidation always occurs at the anode.

045 (part 2 of 2) 10.0 points
If the half-reaction for the anode involves $\mathrm{Fe}^{2+}$ and Fe , which of these redox pairs could be in the cell on the right?

1. $\mathrm{Mn}^{2+}$ and Mn
2. $\mathrm{H}^{+}$and $\mathrm{H}_{2}$
3. None of these can give a voltaic cell
4. $\mathrm{Sn}^{2+}$ and Sn correct
5. $\mathrm{Cr}^{3+}$ and Cr

## Explanation:

Because the $\mathrm{Fe}^{2+} / \mathrm{Fe}$ half-reaction is the anode and this is a galvanic cell, the other halfreaction must have a standard reduction potential that is more positive (higher up on the standard reduction potential table) than that of $\mathrm{Fe}^{2+} / \mathrm{Fe}$. Only two answer choices have a more positive reduction potential: $\mathrm{Sn}^{2+} / \mathrm{Sn}$, and $\mathrm{H}^{+} / \mathrm{H} 2$. But the $\mathrm{H}^{+} / \mathrm{H} 2$ half-reaction has no solid component to serve as an electrode and therefore requires a platinum electrode, and the problem specifies that there are no platinum electrodes. That leaves $\mathrm{Sn}^{2+} / \mathrm{Sn}$ as the only option.

## $046 \quad 10.0$ points

Using an electroplating system operating at 7.35 amps , it take 1.50 hours to plate out 5.00 grams of an unknown metal from its molten chloride salt, $\mathrm{MCl}_{2}$. Identify the metal M .

1. Cu
2. Fe
3. Cd
4. Zn
5. Mg correct

Explanation:
$\frac{I \cdot t}{n \cdot F}=$ moles of metal
$\frac{7.35(1.5 \times 60 \times 60)}{2 \cdot 96485}=.206 \mathrm{~mol}$ metal
molar mass $=5 \mathrm{~g} / .206 \mathrm{~mol}=24.3 \mathrm{~g}$
This matches the molar mass of Mg.

## $047 \quad 10.0$ points

Consider a standard voltaic cell at equilibrium. Which of the following is true?

1. $\mathrm{E}<0, \Delta G>0, K<0$
2. $\mathrm{E}>0, \Delta G>0, K>1$
3. $\mathrm{E}<0, \Delta G>0, K<1$
4. $\mathrm{E}=0, \Delta G=0, K=1$
5. $\mathrm{E}=0, \Delta G=0, K>1$ correct

## Explanation:

For a voltaic cell at equilibrium:

$$
\mathrm{E}=0, \Delta G=0, K>1
$$

It is important to realize here that E and $\Delta G$ are not standard values, so at equilibrium they are equal to zero (think of this voltaic cell as a dead battery).

## $048 \quad 10.0$ points

Consider the following cell:

$$
\mathrm{Pd}\left|\mathrm{Pd}^{2+} \| \mathrm{Ru}^{3+}\right| \mathrm{Ru}
$$

What is $\Delta G^{\circ}$ for the overall cell reaction that is represented here? Balance the reaction using the lowest possible integer values.

1. -91.2 kJ
2. +182 kJ correct
3. +877 kJ
4. -182 kJ
5. +91.2 kJ
6. -877 kJ

## Explanation:

$\mathrm{Pd}^{2+} / \mathrm{Pd}=+0.915 \mathrm{~V}$
$\mathrm{Ru}^{3+} / \mathrm{Ru}=+0.60 \mathrm{~V}$
$E^{\circ}=0.60-0.915=-0.315 \mathrm{~V}$
$\Delta G^{\circ}=-n F E^{\circ}$

$$
\begin{aligned}
& =-6(96485)(-0.315)=+182356 \mathrm{~J} \\
& =+182 \mathrm{~kJ}
\end{aligned}
$$

## $049 \quad 10.0$ points

Use half-reactions from the standard reduction table to calculate the $K_{\mathrm{sp}}$ for $\mathrm{Zn}\left(\mathrm{IO}_{3}\right)_{2}$.

1. $1.7 \times 10^{-26}$
2. $6.8 \times 10^{-32}$
3. $4.8 \times 10^{-12}$
4. $3.9 \times 10^{-6}$ correct
5. $7.3 \times 10^{-19}$

## Explanation:

$\mathrm{Zn}\left(\mathrm{IO}_{3}\right)_{2}+2 \mathrm{e}^{-} \rightarrow \mathrm{Zn}+2 \mathrm{IO}_{3}^{-}$

$$
E^{\circ}=-0.922 \mathrm{~V}
$$

$\mathrm{Zn} \rightarrow \mathrm{Zn}^{2+}+2 \mathrm{e}^{-}$(shown as oxidation)

$$
E^{\circ}=+0.762 \mathrm{~V}
$$

Adding the half-reactions together, we get the solubility reaction for $\mathrm{Zn}\left(\mathrm{IO}_{3}\right)_{2}$ :

$$
\begin{aligned}
& \mathrm{Zn}\left(\mathrm{IO}_{3}\right)_{2} \rightarrow \mathrm{Zn}^{2+}+2 \mathrm{IO}_{3}^{-} \\
& E^{\circ}=-0.922+0.762=-0.160 \mathrm{~V}
\end{aligned}
$$

$K$ for this reaction then will be $K_{\text {sp }}$ for $\mathrm{Zn}\left(\mathrm{IO}_{3}\right)_{2}$.

$$
\begin{aligned}
K_{\mathrm{sp}} & =10^{\frac{n E^{\circ}}{0.05916}} \\
& =10^{\frac{(2)(-0.16)}{0.059916}}=3.9 \times 10^{-6}
\end{aligned}
$$

## $050 \quad 10.0$ points

What is the potential for the following cell?
$\operatorname{In}\left|\mathrm{In}^{3+}(0.010 \mathrm{M})\right| \mid$

$$
\mathrm{Ce}^{4+}(0.50 \mathrm{M}), \mathrm{Ce}^{3+}(0.010 \mathrm{M}) \mid \mathrm{Pt}
$$

1. 2.37 V
2. 1.95 V
3. 1.81 V
4. 2.02 V
5. 2.09 V correct

## 6. 1.88 V

## Explanation:

Rxn: $3 \mathrm{Ce}^{4+}+\mathrm{In} \rightarrow \mathrm{In}^{3+}+3 \mathrm{Ce}^{3+}$
$E^{\circ}=1.61-(-0.34)=1.95 \mathrm{~V}$
$Q=\frac{\left[\mathrm{Ce}^{3+}\right]^{3}\left[\mathrm{In}^{3+}\right]}{\left[\mathrm{Ce}^{4+}\right]^{3}}=\frac{(0.01)^{3}(0.01)}{(0.5)^{3}}$
$=8.0 \times 10^{-8}$
$E=1.95-\frac{0.05916}{3} \log \left(8.0 \times 10^{-8}\right)=2.09 \mathrm{~V}$
