This exam should have exactly 25 questions. Each question is equally weighted at 4 points each. You will enter your answer choices on the virtual bubblehseet after you have finished. Your score is based on what you submit on the virtual bubblesheet and not what is circled on the exam.

1. What is the cell potential for the following nonstandard cell?

$$Ni \mid Ni^{2+} (1M) \mid Ag^{+} (0.0065M) \mid Ag$$

- a. 0.622 V
- b. 0.460 V
- c. 0.332 V
- d. 1.160 V
- ●e. 0.901 V
- f. 0.771 V

Explanation:  $E^{\circ} = +0.800 - -0.230 = +1.03 \text{ V}.$   $Q = \frac{1}{0.0065^2} \text{ and } n = 2$   $E = 1.03 - 0.05916/2 \log(\frac{1}{0.0065^2})$ E = 0.901 V

- 2. You go to the hardware store to buy some root killer (copper(II) sulfate, 159.6 g/mol) and to your dismay it is all sold out. Using your electrochemistry knowledge, you decide to make some yourself. You instead buy copper piping and sulfuric acid to construct an electrolytic cell. Copper(II) sulfate is deposited on the copper electrode from a solution of sulfuric acid. What mass of copper(II) sulfate is made when 27.0 amps of current is run continuously for 17.0 hours?
- a. 1.13 kg
- •b. 1.37 kg
  - c. 22.8 g
  - d. 1.76 kg
  - e. 308 g
  - f. 672 g

**Explanation:** The oxidation number of copper sulfate is +2, so you need to lose 2 mols of electrons per mol of copper to make Cu(II). Now use  $mol = \frac{I \cdot t}{n \cdot F} = \frac{(27) \cdot (17*60*60)}{2.96458} = 8.56$  mols of CuSO<sub>4</sub>. Use MW to convert into g and then into kg to find 1.37 kg.

- 3. Salts of chromate  $(CrO_4^{2-})$  are incredibly toxic and carcinogenic because they mimic phosphate  $(PO_4^{3-})$ , which forms backbone of DNA. What is the oxidation number of Cr in chromate and P in phosphate, respectively?
- •a. +6 and +5
  - b. +6 and +6
  - c. +5 and +5
  - d. +5 and +6
  - e. +8 and +8

**Explanation:** For  $CrO_4^{2-}$ , each oxygen is 2-, but the overall complex has a 2- charge, making the Cr 6+. For  $PO_4^{3-}$ , each oxygen is again -2, but this time the overall molecule has a 3- charge, making the P 5+.

- 4. Which type of battery chemistry listed below results in a battery that is not rechargeable?
- a. NiMH

explin: NiCd, Pb-acid, Li-ion, and NiMH are all examples of secondary cells (rechargeable) batteries. The only one that is a primary (non-rechargable) battery is an alkaline cell.

- b. Li-ion
- c. alkaline
- d. NiCd
- e. Pb-acid

## **Explanation:**

5. We construct the following cell below and measure the potential to be 1.610 V. What is the concentration of  $Mn^{2+}$  ions?

$$Mn \mid Mn^{2+} (? M) \mid | Cu^{2+}(2M) \mid Cu$$

- a. 0.110 M
- b. 0.256 M
- •c. 0.0018 M
- d. 0.0073 M
- e. 0.767 M

**Explanation:** Use Nernst equation:

$$E = E^{\circ} - \frac{0.05916}{2} \log Q$$

$$E^{\circ} = E^{\circ}_{cathode} - E^{\circ}_{anode} = 0.340V - (-1.180V) = 1.520V$$

$$1.610 = 1.520 - \frac{0.05916}{2} \log(\frac{x}{2})$$

Solve for x = 0.0020 M

**6**. Consider the following redox reaction:

$$Ta^{4+}(aq) + Co(s) \longrightarrow Ta^{2+}(aq) + Co^{2+}(aq)$$

What is the reducing agent?

- a.  $Ta^{4+}$
- b. Co<sup>2+</sup>
- •c. Co
  - $d. Ta^{2+}$

**Explanation:** The reducing agent is the species being oxidized, which is Co(s) being oxidized to  $Co^{2+}$ .

- 7. How long will it take to deposit 0.0231 moles of solid promethium (Pm, atomic number 61) by the electrolysis of Pm(NO<sub>3</sub>)<sub>3</sub>(aq) using a current of 1.31 A?
- a. 80 minutes
- b. 70 minutes
- c. 75 minutes
- d. 65 minutes
- •e. 85 minutes
- f. 60 minutes

**Explanation:** First note that the oxidation number of promethium is +3 in the aqueous solution given, so when it gets reduced to solid promethium, 3 moles of electrons will be transferred. Now use  $t = \frac{mol \cdot n \cdot F}{I} = \frac{0.0231(3)(96485)}{1.31} = 5100 \text{ s} = 85 \text{ minutes}$ 

8. (part 1 of 2): Consider the electrochemical cell diagram shown below which is running with the electron flow direction as shown. What must be true for this electrochemical cell to run a complete closed-loop (circular) circuit without creating an imbalance of charge?

- a. anions must flow from y toward z, cations flow from y toward x
- b. anions must flow from y toward x, cations flow from y toward z
- c. anions must flow from p toward z, cations flow from p toward x
- •d. anions must flow from p toward x, cations flow from p toward z
- e. anions must flow from p toward x, cations flow from y toward z

**Explanation:** p = salt bridge; cations will flow towards the cathode which has to be the z component due to the fact electrons are flowing towards it in the external circuit. Anions will flow to x, which is the anode compartment.

- **9.** (part 2 of 2): Suppose the previously shown cell diagram represents an electrolytic cell. What is the role and assigned charge of the component labeled *z*?
- a. cathode, positive
- b. anode, positive
- •c. cathode, negative
  - d. cathode, no charge
  - e. anode, negative

**Explanation:** Electrons always travel from anode to cathode. For the diagram given, the electrons travel from x (anode) to z (cathode). For an electrolytic cell, the anode is positive (x) and the cathode is negative (z).

10. What is the standard free energy change for the following standard cell?

- a. +40.5 kJ
- b. +45.3 kJ
- •c. −90.7 kJ
- d. -45.3 kJ
- e. -40.5 kJ
- f. +90.7 kJ

**Explanation:** We can relate the cell potential to the standard free energy change using one of the triforce relationships:  $-nF\mathcal{E}^{\circ} = \Delta G^{\circ}$ .

Recognize that Pb is the anode and Cu is the cathode:  $\mathcal{E}^{\circ} = \mathcal{E}^{\circ}_{\text{constant}} - \mathcal{E}^{\circ}_{\text{constant}} = 0.340 \text{ V} - (-0.130 \text{ V}) = 0.470 \text{ V}$  Rearrange the above realtionship and solve for  $\Delta G^{\circ} = -90.7 \text{ kJ}$ 

- 11. Which of the following metals is most easily oxidized?
- a. Cu
- b. Ni
- c. Ag
- d. Au
- ●e. Al

**Explanation:** The metal that is most easily oxidized is the one with the greatest oxidation potential. The table provided shows reduction potentials for ions associated with these metals. The oxidation potential of the metal is the opposite of the standard reduction potential of the associated ions.

12. Balance the following redox reaction in acidic solution:

$$Ru^{3+} + IO_4^- \longrightarrow RuO_4 + I^-$$

What is the coefficient of Ru<sup>3+</sup> in the simplest, overall reaction?

- a. 6
- •b. 8
- c. 2
- d. 5
- e. 1
- f. 4

## **Explanation:**

 $12 H_2 O + 8 Ru^{3+} + 5 IO_4^- \longrightarrow 8 RuO_4 + 5 I^- + 24 H^+$ Coefficient on  $Ru^{3+}$  is 8.

- 13. What is the reducing agent in an alkaline cell?
- a.  $MnO_2$  (s)
- b.  $H_2O(\ell)$
- c.  $Mn_2O_3$  (s)
- •d. Zn (s)
  - e. ZnO (s)

**Explanation:** The overall reaction for an alkaline cell is  $2MnO_2 + Zn \longrightarrow Mn_2O_3 + ZnO$  Zn changes its oxidation state from 0 to +2 and is thus oxidized and the reducing agent is the reactant that itself undergoes oxidation. It's the reactant that "gives away" electrons.

- 14. Car batteries from the 1970's were able to produce about 300 cold cranking amps. Modern car batteries are able to produce well over 600 cold cranking amps. This improvement in performance is mostly due to:
- a. Batteries from the 1970's used lead (II) sulfate, modern batteries now use lead (II) nitrate.
- b. Batteries from the 1970's used  $PbO_2$  as the oxidant, modern batteries now use  $TiO_2$ .
- c. The use of higher purity lead in batteries.
- d. The design of improved electrodes with higher surface area.
  - e. Lead from the 1970's was just lazy.

**Explanation:** Car batteries from the 1970's and modern car batteries operate off of the exact same electrochemical reaction. The improvement in current output is largely due to the design improved electrodes with increased surface area.

## 15. Consider the cell:

$$Pt(s) \mid H_2(g) \mid H^+(aq) \mid Cl^-(aq) \mid Cl_2(g) \mid C(s)$$

What is serving as the anode in this electrochemical cell?

- a. C(s)
- b.  $H_2(g)$
- c.  $Cl_2(g)$
- d.  $Cl^{-}(aq)$
- •e. Pt(s)
  - f.  $H^+(aq)$

**Explanation:** When using standard cell notation, the solid to the furthest left side of the notation is solid substance serving as the anode.

- 16. Which of the following species is the strongest reducing agent?
- a. Ag(s)
- b.  $F_2(g)$
- c. Cu(s)
- •d. Zn(s)
  - e.  $Mg^{2+}(aq)$

**Explanation:** A good reducing agent needs to push electrons away which means they will be on the right side of a standard potential table and will have the most negative  $E^{\circ}$ . That means that Zn is the best of those listed.

- 17. Which of the following is true of a standard hydrogen electrode?
  - I. It cannot be part of a voltaic cell since its standard reduction potential is zero.
- II. It contains a solution with a concentration of  $[H^+] = 1 M$
- III. It uses  $H_2$  gas at a pressure of 1 atm.
- a. I, II and III
- b. only III
- c. I and II
- d. only I
- e. II and III
- f. only II
- g. I and III

**Explanation:** SHE is used as a reference for all other half-reactions, and is zero by definition. That does not mean that it cannot be used in a cell. By definition, the solution must have 1 M  $\rm H^+$  and the  $\rm H_2$  pressure must be 1 atm. Thus, the correct answers are only II and III.

18. Consider the following redox reaction involving curium (An element whose namesake honors Marie Curie, a pioneering chemist and physicist who studied radioactivity) and the unfortunately named Uranate ion,  $UO_4^{2-}$ .

$$Cm(s) + UO_4^{2-}(aq) \longrightarrow Cm^{3+}(aq) + UO_2(s)$$

Using the smallest possible integer coefficients, balance the reaction in acidic aqueous solution. What is the coefficient for H<sup>+</sup>, and which side of the reaction is it on?

- •a. 12, left
  - b. 10, right
- c. 2, left
- d. 12, right
- e. 10, left
- f. 4, left

## **Explanation:**

$$2Cm + 3UO_4^{2-} + 12H^+ \longrightarrow 2Cm^{3+} + 3UO_2 + 6H_2O$$

Coefficient on H<sup>+</sup> is 12, and is on the left.

- 19. A proposed solution for grid-scale energy storage is the use of so-called 'flow batteries'. They are essentially just warehouse sized electrochemical cells! They can be charged by running the cell electrolytically, and can later be discharged by running the cell voltaically. A common cell design uses the  $\rm Cr^{2+}/\rm Cr^{3+}$  and  $\rm Fe^{2+}/\rm Fe^{3+}$  redox couples. What is the standard cell potential for a voltaic cell constructed using these redox couples?
- •a. +1.18 V
  - b. -1.18 V
  - c. 0.033 V
  - d. -0.36 V
  - e. 1.68 V
  - f. +0.36 V

**Explanation:** The standard reduction potentials are -0.407 V for  $\text{Cr}^{2+}/\text{Cr}^{3+}$  and 0.771 for  $\text{Fe}^{2+}/\text{Fe}^{3+}$ . We are running a voltaic cell, so we assign the more negative potential to be the anode  $(\text{Cr}^{2+}/\text{Cr}^{3+})$  and the more positive potential to be the cathode  $(\text{Fe}^{2+}/\text{Fe}^{3+})$ , giving us a potential of +1.18 V.

20. The following concentration cell has a measured potential of +84.8 mV. What is the unknown chromium(II) ion concentration in this cell?

$$\operatorname{Cr} \mid \operatorname{Cr}^{2+} (1.7 \times 10^{-4} \text{ M}) \mid \mid \operatorname{Cr}^{2+} (? \text{ M}) \mid \operatorname{Cr}$$

- •a. 0.125 M
  - b.  $2.0 \times 10^{-6} \text{ M}$
  - c.  $3.2 \times 10^{-8} \text{ M}$
- d. 0.14 M
- e. 0.075 M
- f. 0.0023 M

**Explanation:** Use Nernst equation:

$$E = E^{\circ} - \frac{0.05916}{2} \log Q$$

$$0.0848 = 0 - (0.02958) \log(\frac{1.7 \times 10^{-4}}{x})$$

solve for  $x = 0.125 \text{ M} = [Cr^{2+}]$  in the cathode compartment

- 21. Identify the oxidation number for each element in MnSO<sub>4</sub>. List your answer in the order Mn, S, and O.
- a. +2, +8, -2
- b. +2, +4, -6
- c. +4, +3, -1
- •d. +2, +6, -2
- e. +2, +5, -2

**Explanation:** Oxygen has an oxidation number of -2. The polyatomic sulfate anion has an overall charge of -2, so sulfurs's oxidation number be -6 in order to compensate for the four oxygen ions. The manganese is given as manganese(II) ion, so its oxidation number in considered to be +2.

22. For the following reaction of titanium(III) chloride with fluorine, what is the oxidizing agent?

$$3\text{TiCl}_3(aq) + 3\text{F}_2(g) \rightarrow 3\text{TiF}_3(aq) + 3\text{Cl}_2(g)$$

- a.  $TiCl_3(aq)$
- b.  $TiF_3(aq)$
- c.  $Cl_2(g)$
- •d.  $F_2(g)$ 
  - e. Ti(aq)

**Explanation:** Fluorine is being reduced from an oxidation state of 0 to a state of -1, so it is causing the chloride ion to be oxidized.

- 23. You hook up a voltmeter to a standard electrochemical cell and it reads +0.313 V. With this information, which of the following is true regarding this cell?
- a.  $\Delta G$  is positive and K is greater than 1.
- b.  $\Delta G$  is negative and K is less than 1.
- c.  $\Delta G$  is positive and K is less than 1.
- d.  $\Delta G$  is zero and K is equal to 1.
- •e.  $\Delta G$  is negative and K is greater than 1.

**Explanation:** Recall the triforce,  $-nF\mathcal{E}^{\circ} = \Delta G^{\circ} = -RTlnK$ . If we measure a positive potential, this must correspond to a negative  $\Delta G^{\circ}$  (a spontaneous process). This must also correspond to an equilibrium constant which is greater than 1.

- **24.** I put a piece of copper wire into a solution of 1 M Ag<sup>+</sup>. What happens?
- a. The two reactants will fuse together to make Zn metal.
- •b. The copper wire reduces the Ag<sup>+</sup> ions to silver metal.
- c. The copper ions in solution are reduced and plate onto the copper wire
- d. Nothing will happen.

**Explanation:** The standard potential for Cu(s) and Ag<sup>+</sup>(aq) is 0.46 V. This is spontaneous, so the copper wire will be oxidized and the silver ions will be reduced.

- 25. In an electrolytic cell, the positive terminal is the \_\_\_\_ and is the site of the \_\_\_\_ half-reaction.
- a. cathode; oxidation
- b. anode; reduction
- •c. anode; oxidation
  - d. cathode; reduction

**Explanation:** In an electrolytic cell (analogous to charging a battery), the cathode is always attributed a negative sign and the anode a positive sign. By definition, the cathode is the site of reduction, and the anode is the site of oxidation.

After you are finished and have all your answers circled, go to the front of the room and then use the QR code show below to pull up the virtual answer page for your exam. Enter the appropriate info plus all your answers - click the SUBMIT button. Double check your choices on the next page. Once your are sure, click the submit button on that page to enter your answers. Make sure you get the confirmation screen (different background color!) and show it to the TA or proctor. After that, turn in your exam and scratch paper. You're free to leave after that.
